

Safitza Group.

Vein 7 of the hindwing in the ♂ arises midway between veins 6 and 8 or even nearer to 8, rarely somewhat nearer to 6, but never twice as far from 8 as from 6. Vein 7 is furthest removed from vein 8 in *M. danckelmanni* and *tolosa*. The forewing of the ♂ in almost all the species has in cellule 1a close behind vein 1 a small, rounded or elongate mealy spot, raised like a wart or weal. — The numerous species of this group are often very much alike and the ♀♀ especially can sometimes only be determined with difficulty if one does not also possess the corresponding ♂♂. In order to facilitate the determination of the species I divide them into several subgroups, chiefly based on the pencils and mealy spots of the ♂♂.
